Independent medicine is drowning in unpaid computer work

2 hrs

of desk + EHR work for every 1 hour of direct patient care

Sinsky et al., Annals of Internal Medicine (AMA time-motion study)

\$9.8M

average cost of a healthcare data breach — the costliest industry 14 years running

IBM Cost of a Data Breach Report, 2024

31M+

patients depend on community health centers that run on thin margins

HRSA Health Center Program data, 2023

Behind every stat is the same clinic: no IT department, no compliance officer, no enterprise software budget — and a front-desk laptop holding thousands of patient records. The paperwork burden falls on the clinicians who can least afford the time, at the practices that can least afford the tools.

The clinics that need AI most are the ones that can't use it

COST

Cloud AI scribes and document tools list at roughly \$99–\$600 per clinician per month. A safety-net clinic with five providers is looking at up to \$36k a year — for one tool.

COMPLIANCE

Consumer AI tools won't sign a Business Associate Agreement. Pasting a patient note into a chatbot isn't a shortcut — it's a HIPAA disclosure. The upload is the breach.

CAPACITY

Enterprise AI assumes an IT department to vet vendors, manage deployments, and harden machines. Most small practices have nobody whose job that is.

Open weights changed the math. Gemma 4 (Apache-2.0) now runs frontier-grade reasoning on a stock laptop — no account, no per-seat fee, no data leaving the building. For the first time, the fast tool and the compliant tool are the same tool.

One engine. Four prongs. Every byte stays in the building.

Every prong runs the same trust loop:

The visit writes itself — and never leaves the room

- **Capture the encounter on-device.** Local speech-to-text runs on the clinic's own laptop — the audio file never touches a server, so there is no third party and no BAA to sign.
- **Gemma drafts the note.** The transcript is structured into a SOAP-style draft — subjective, objective, assessment, plan — ready for the clinician to edit and sign.
- **The clinician stays the author.** Nothing enters the chart without review and an explicit click. The AI drafts; the doctor decides.
- **A proven market — priced for the big systems.** Investors put \$300M+ into cloud ambient scribes in 2024 alone: Abridge (\$150M at an \$850M valuation), Suki (\$70M), Ambience, Nabla — all sold to large health systems. Obscura brings the capability to everyone else, free. (Business Insider, Oct 2024)

WHY ON-DEVICE WINS HERE

Visit audio is the most sensitive PHI a clinic creates.

Cloud scribe: audio → vendor server → BAA, subprocessors, retention policies to audit.

Obscura: audio → this laptop → note. The privacy review is one sentence long.

Status: in design — the newest prong of the four. REDACT, SECURE and ORGANIZE are working today.

Share the record, not the patient

- **Built on the HIPAA Safe Harbor standard.** Detection is mapped to all 18 identifier categories of 45 CFR 164.514(b)(2)(i) — names, MRNs, member IDs, dates, geography and the rest — with a live coverage panel per document.
- **Hybrid detection, on purpose.** Pure-LLM PII detection averages ~0.54 F1. Obscura runs deterministic rules (SSN, Luhn, MRN, phone) for perfect precision, and Gemma 4 for names, addresses and context — grounded to exact pixels by OCR.
- **Destroys, never covers.** Pages are rasterized, boxes burned into pixels, metadata stripped — an image-only PDF with no text layer to copy out.

IT CHECKS ITS OWN WORK

4-part verification battery on every export:

- ① Select-all test — zero selectable characters
- ② Text-search — no redacted string findable
- ③ Re-OCR — nothing readable survives in pixels
- ④ Metadata audit — document dictionary empty

Downloadable compliance report, per document.

Coverage audit is technical QA, not legal advice — a human reviewer still signs off, exactly as Safe Harbor requires.

A \$0 IT department for the front-desk laptop

- **Finds what an auditor would.** Read-only scan for plaintext passwords and keys on disk, weak OS configuration, and risky open ports — the everyday exposures behind real clinic breaches.
- **Grounded in CIS hardening checks.** Findings map to CIS Level 1 benchmark checks, rolled into a single plain-English Safety Score anyone at the front desk can read.
- **Explains, never executes.** Gemma turns each finding into one sentence of “what this means and why it matters.” Fixes come from a hardcoded registry — the model never runs anything.
- **Performance, too.** The same scan flags what slows aging hardware — startup bloat, low disk, pending updates — so the one clinic laptop stays usable.

WHAT A SCAN RETURNS

Safety Score: 62 → 91 after fixes

- API key in plaintext on Desktop → “Send to Redactor”
- Disk encryption off on PHI volume
- Remote-desktop port open to network
- 14 startup apps slowing boot

Every fix described in plain English. You click; it never acts alone.

Defensive by design: it scans only your own machine, read-only, and describes fixes — it does not attack, probe networks, or auto-remediate.

Files that name themselves

- **Gemma reads page one.** For each file it reads a cheap signature — first page of a PDF, first rows of a sheet, or the image itself — and returns doc-type, entity, date and a descriptor.
- **Code enforces the template.** The model supplies understanding only; a deterministic naming template builds the final name, so results are consistent every time.
- **Crash-safe and reversible.** Moves run through a journaled, atomic operation — never a delete — and one-click Undo replays the whole reorganization in reverse.
- **Approve before anything moves.** The full folder proposal is shown first; nothing happens until the human says yes.

BEFORE → AFTER

A findable record is a safer record — files you can locate are files you can protect, redact, and produce on request.

A Tuesday at a two-provider clinic

Notes and redacted records export as standard PDFs today; EHR integration is the roadmap's next mile — the moat the cloud vendors built closed, we build open.

Everyone else is in the cloud — and priced for the big systems

THE OPEN QUADRANT

Every funded player sells cloud AI to institutions.

On-device + built-for-everyone is empty — because there was no business model for it.

Open source is the business model.

Positioning per Business Insider funding coverage, Oct 2024; company placements approximate.

What a small clinic pays for this today

AI scribe

\$299–\$1,512 per clinician / month

Suki \$299–399 · DAX Copilot list \$1,512 (typ. \$369–830 + \$5k–50k setup) · budget tier: Freed \$79–119

Redaction software

\$279–\$379 per user / month

CaseGuard Doc/Ultimate suites · budget tier: Redactable from \$278/yr

Managed IT + HIPAA

\$100–\$250 per user / month

small-practice HIPAA-ready managed IT; HIPAA compliance support adds \$15–30/user

File & records admin

staff hours every single day

manual naming, filing, and hunting for documents — unpriced but paid in time

OBSCURA

\$0

per clinician · per month · forever

Apache-2.0, on hardware the clinic already owns. A 2-provider clinic replaces \$15,000+ a year of the stack at left.

The market says the pain is real: AI clinical documentation is a \$1.2–2.8B market today, forecast to reach ~\$15B by 2034–35 (19–29% CAGR across analyst houses). All of it cloud. None of it priced for small practices.

Pricing: vendor list/published reseller pages + 2026 pricing guides (Freed, Suki, Microsoft/Nuance, CaseGuard, Redactable, MSP surveys); market size: Dataintel, Astute Analytica, SNS Insider, Grand View 2025–26 reports. Ranges are list prices, verify per quote.

Privacy you can watch. Safety by architecture.

External connections: 0

A live egress panel lists every network connection the app holds. Run it with Wi-Fi off — everything still works. That's the proof, not a promise.

Human-in-the-loop, everywhere

No redaction, no file move, no machine change without an explicit click. The AI proposes; a person disposes.

Verification is a feature

REDACT re-opens its own output and attacks it. ORGANIZE journals every move for Undo. The tool assumes it made a mistake and checks.

THE PRONGS FEED EACH OTHER

SECURE

finds a plaintext
key on disk

REDACT

destroys it —

result

TRANSCRIBE

feeds notes into
the same loop

Built, demoed, and self-verified — in a one-day sprint

GDG “Build & Hack with Gemma 4.0” — Newport Beach, July 2026

3 / 4

prongs working end-to-end today — REDACT, SECURE, ORGANIZE — on synthetic demo data

0

recoverable characters after redaction: select-all, text-search, re-OCR and metadata checks all pass

16/18

HIPAA Safe Harbor identifier categories flagged on a synthetic patient record, shown in the coverage panel

8 GB

of laptop GPU is enough — hardware probe auto-selects the right Gemma 4 variant per machine

Open code, open license: github.com/meetkpatel/Obscura · Apache-2.0, mirroring Gemma 4’s own license · all demo data synthetic — no real PHI, ever

Frontier AI shouldn't be a luxury good.

The practices serving the most vulnerable patients deserve the same AI leverage as the biggest health systems — without the subscription, the BAA, or the data leaving the building. Open-source models finally make that possible. Obscura is the wrapper that makes it usable.

NOW

Ship the TRANSCRIBE prong — on-device visit notes

NEXT

One-click installer + pilots with community clinics

THEN

The same four prongs for legal aid, social work, schools

The ask: pilot clinics to shape TRANSCRIBE · open-source contributors · EHR-integration partners

As fast as AI. As private as a locked filing cabinet.

github.com/meetkpatel/Obscura · Apache-2.0 · built on Gemma 4
